

PARTIAL DERIVATIVES

In Example 6 of rectangular box, we maximized a volume function V = xyz subject to the constraint 2xz + 2yz + xy = 12—which expressed the side condition that the surface area was 12 m^2 .

PARTIAL DERIVATIVES

In this section, we present Lagrange's method for maximizing or minimizing a general function f(x, y, z) subject to a constraint (or side condition) of the form g(x, y, z) = k.

PARTIAL DERIVATIVES

Lagrange Multipliers

In this section, we will learn about:

Lagrange multipliers for two and three variables,
and given one and two constraints.

LAGRANGE MULTIPLIERS

It's easier to explain the geometric basis of Lagrange's method for functions of two variables.

LAGRANGE MULTIPLIERS—TWO VARIABLES

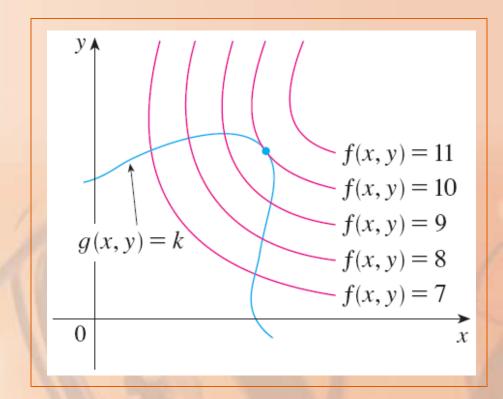

So, we start by trying to find the extreme values of f(x, y) subject to a constraint of the form g(x, y) = k.

■ In other words, we seek the extreme values of f(x, y) when the point (x, y) is restricted to lie on the level curve g(x, y) = k.

LAGRANGE MULTIPLIERS—TWO VARIABLES

The figure shows this curve together with several level curves of *f*.

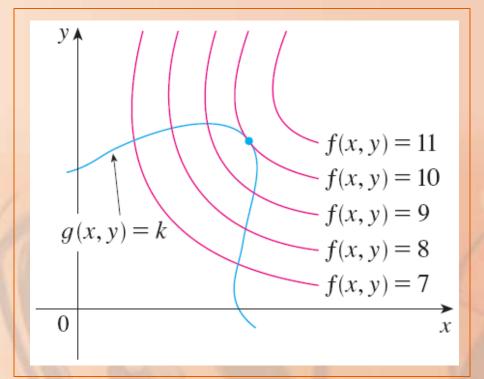

These have the equations f(x, y) = c, where c = 7, 8, 9, 10, 11

LAGRANGE MULTIPLIERS—TWO VARIABLES

To maximize f(x, y) subject to g(x, y) = k is to find:

The largest value of c such that the level curve f(x, y) = c intersects g(x, y) = k.

LAGRANGE MULTIPLIERS—THREE VARIABLES

This kind of argument also applies to the problem of finding the extreme values of f(x, y, z) subject to the constraint g(x, y, z) = k.

■ Thus, the point (x, y, z) is restricted to lie on the level surface S with equation g(x, y, z) = k.

LAGRANGE MULTIPLIERS—METHOD

To find the maximum and minimum values of f(x, y, z) subject to the constraint g(x, y, z) = k [assuming that these extreme values exist and $\nabla g \neq \mathbf{0}$ on the surface g(x, y, z) = k], we proceed as follows.

LAGRANGE MULTIPLIERS—METHOD

a. Find all values of x, y, z, and λ such that

and
$$\nabla f(x, y, z) = \lambda \nabla g(x, y, z)$$
$$g(x, y, z) = k$$

- b. Evaluate f at all the points (x, y, z) that result from step a.
 - The largest of these values is the maximum value of f.
 - The smallest is the minimum value of f.

In deriving Lagrange's method, we assumed that $\nabla g \neq 0$.

In each of our examples, you can check that at all points where g(x, y, z) = k.

If we write the vector equation $\nabla f = \lambda \nabla g$ in terms of its components, then the equations in step a become:

$$f_x = \lambda g_x$$
 $f_y = \lambda g_y$ $f_z = \lambda g_z$ $g(x, y, z) = k$

- This is a system of four equations in the four unknowns x, y, z, and λ .
- However, it is not necessary to find explicit values for λ.

For functions of two variables, the method of Lagrange multipliers is similar to the method just described.

To find the extreme values of f(x, y) subject to the constraint g(x, y) = k, we look for values of x, y, and λ such that:

$$\nabla f(x,y) = \lambda \nabla g(x,y)$$
 and $g(x,y) = k$

This amounts to solving three equations in three unknowns:

$$f_x = \lambda g_x$$
 $f_y = \lambda g_y$ $g(x, y) = k$

Our first illustration of Lagrange's method is to reconsider the problem given in Example 6 in Section 14.7 (Thomas Calculus)

Example 1

A rectangular box without a lid is to be made from 12 m² of cardboard.

Find the maximum volume of such a box.

Example 1

As in Example 6 in Section 14.7, we let x, y, and z be the length, width, and height, respectively, of the box in meters.

■ Then, we wish to maximize V = xyz subject to the constraint

$$g(x, y, z) = 2xz + 2yz + xy = 12$$

Example 1

Using the method of Lagrange multipliers, we look for values of x, y, z, and λ such that:

$$\nabla V = \lambda \nabla g$$
 and $g(x, y, z) = 12$

This gives the equations

$$V_{x} = \lambda g_{x}$$

$$V_{y} = \lambda g_{y}$$

$$V_{z} = \lambda g_{z}$$

$$2xz + 2yz + xy = 12$$

The equations become:

$$yz = \lambda(2z + y)$$

$$xz = \lambda(2z + x)$$

$$xy = \lambda(2x + 2y)$$

$$2xz + 2yz + xy = 12$$

Example 1

There are no general rules for solving systems of equations.

Sometimes, some ingenuity is required.

Example 1

In this example, you might notice that if we multiply Equation 2 by x, Equation 3 by y, and Equation 4 by z, then left sides of the equations will be identical.

Doing so, we have:

$$xyz = \lambda(2xz + xy)$$

$$xyz = \lambda(2yz + xy)$$

$$xyz = \lambda(2xz + 2yz)$$

Example 1

We observe that $\lambda \neq 0$ because $\lambda = 0$ would imply yz = xz = xy = 0 from Equations 2, 3, and 4.

This would contradict Equation 5.

Therefore, from Equations 6 and 7, we have

$$2xz + xy = 2yz + xy$$

which gives xz = yz.

- However, $z \neq 0$ (since z = 0 would give V = 0).
- Thus, *x* = *y*.

From Equations 7 and 8, we have

$$2yz + xy = 2xz + 2yz$$

which gives 2xz = xy.

■ Thus, since $x \neq 0$, y = 2z.

If we now put x = y = 2z in Equation 5, we get:

$$4z^2 + 4z^2 + 4z^2 = 12$$

- Since x, y, and z are all positive, we therefore have z = 1, and so x = 2 and y = 2.
- This agrees with our answer in Section 14.7

Another method for solving the system of equations 2–5 is to solve each of Equations 2, 3, and 4 for λ and then to equate the resulting expressions.

Find the extreme values of the function $f(x, y) = x^2 + 2y^2$ on the circle $x^2 + y^2 = 1$.

 We are asked for the extreme values of f subject to the constraint

$$g(x, y) = x^2 + y^2 = 1$$

Using Lagrange multipliers, we solve the equations $\nabla f = \lambda \nabla g$ and g(x, y) = 1.

These can be written as:

$$f_{x} = \lambda g_{x}$$

$$f_{y} = \lambda g_{y}$$

$$g(x, y) = 1$$

E. g. 2—Eqns. 9-11

They can also be written as:

$$2x = 2x\lambda$$

$$4y = 2y\lambda$$

$$x^2 + y^2 = 1$$

From Equation 9, we have

$$x = 0$$
 or $\lambda = 1$

- If x = 0, then Equation 11 gives $y = \pm 1$.
- If $\lambda = 1$, then y = 0 from Equation 10; so, then Equation 11 gives $x = \pm 1$.

Therefore, *f* has possible extreme values at the points

$$(0, 1), (0, -1), (1, 0), (-1, 0)$$

Evaluating f at these four points, we find that:

$$f(0, 1) = 2$$
 $f(0, -1) = 2$ $f(1, 0) = 1$ $f(-1, 0) = 1$

Therefore, the maximum value of f on the circle $x^2 + y^2 = 1$ is:

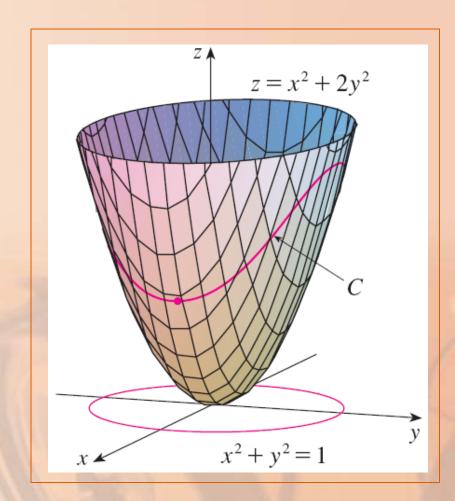

$$f(0, \pm 1) = 2$$

The minimum value is:

$$f(\pm 1, 0) = 1$$

Example 2

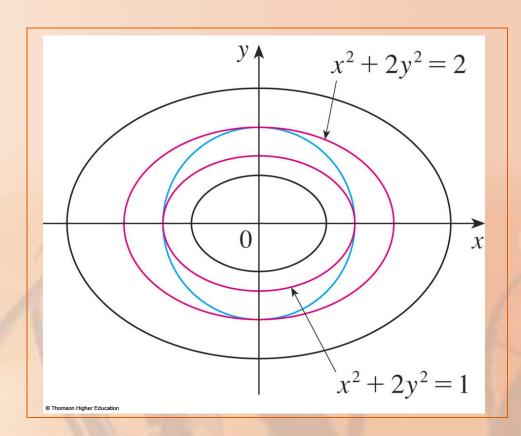

Checking with the figure, we see that these values look reasonable.

LAGRANGE'S METHOD

The geometry behind the use of Lagrange multipliers in Example 2 is shown here.

■ The extreme values of $f(x, y) = x^2 + 2y^2$ correspond to the level curves that touch the circle $x^2 + y^2 = 1$

Find the extreme values of

$$f(x, y) = x^2 + 2y^2$$
 on the disk $x^2 + y^2 \le 1$

• According to the procedure in Equation 9 in Section 14.7, we compare the values of f at the critical points with values at the points on the boundary. Since $f_x = 2x$ and $f_y = 4y$, the only critical point is (0, 0).

• We compare the value of f at that point with the extreme values on the boundary from Example 2:

$$f(0, 0) = 0$$
 $f(\pm 1, 0) = 1$ $f(0, \pm 1) = 2$

Therefore, the maximum value of f on the disk $x^2 + y^2 \le 1$ is:

$$f(0, \pm 1) = 2$$

The minimum value is:

$$f(0, 0) = 0$$

Find the points on the sphere $x^2 + y^2 + z^2 = 4$ that are closest to and farthest from the point (3, 1, -1).

The distance from a point (x, y, z) to the point (3, 1, -1) is:

$$d = \sqrt{(x-3)^2 + (y-1)^2 + (z+1)^2}$$

However, the algebra is simpler if we instead maximize and minimize the square of the distance:

$$d^{2} = f(x, y, z)$$

$$= (x-3)^{2} + (y-1)^{2} + (z+1)^{2}$$

The constraint is that the point (x, y, z) lies on the sphere, that is,

$$g(x, y, z) = x^2 + y^2 + z^2$$

= 4

According to the method of Lagrange multipliers, we solve:

$$\nabla f = \lambda \nabla g, g = 4$$

That gives:

$$2(x-3)=2x\lambda$$

$$2(y-1)=2y\lambda$$

$$2(z+1)=2z\lambda$$

$$x^2 + y^2 + z^2 = 4$$

LAGRANGE'S METHOD

Example 4

The simplest way to solve these equations is to solve for x, y, and z in terms of λ from Equations 12, 13, and 14, and then substitute these values into Equation 15.

From Equation 12, we have:

$$x-3=x\lambda$$
 or $x(1-\lambda)=3$ or $x=\frac{3}{1-\lambda}$

■ Note that $1 - \lambda \neq 0$ because $\lambda = 1$ is impossible from Equation 12.

Similarly, Equations 13 and 14 give:

$$y = \frac{1}{1 - \lambda} \qquad z = -\frac{1}{1 - \lambda}$$

So, from Equation 15, we have:

$$\frac{3^2}{(1-\lambda)^2} + \frac{1^2}{(1-\lambda)^2} + \frac{(-1)^2}{(1-\lambda)^2} = 4$$

- This gives $(1 \lambda)^2 = 11/4$, $1 \lambda = \pm \sqrt{11/2}$
- Thus,

$$\lambda = 1 \pm \frac{\sqrt{11}}{2}$$

These values of λ then give the corresponding points (x, y, z):

$$\left(\frac{6}{\sqrt{11}}, \frac{2}{\sqrt{11}}, -\frac{2}{\sqrt{11}}\right)$$
 and $\left(-\frac{6}{\sqrt{11}}, -\frac{2}{\sqrt{11}}, \frac{2}{\sqrt{11}}\right)$

It's easy to see that f has a smaller value at the first of these points. Thus, the closest point is:

$$(6/\sqrt{11},2/\sqrt{11},-2/\sqrt{11})$$

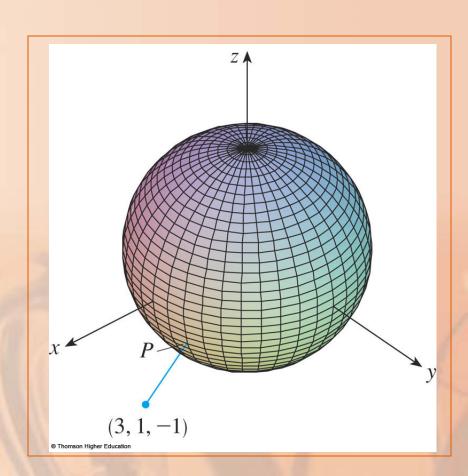

The farthest is:

$$\left(-6/\sqrt{11}, -2/\sqrt{11}, 2/\sqrt{11}\right)$$

LAGRANGE'S METHOD

The figure shows the sphere and the nearest point in Example 4.

 Can you see how to find the coordinates of P without using calculus?

Suppose now that we want to find the maximum and minimum values of a function f(x, y, z) subject to two constraints (side conditions) of the form g(x, y, z) = kand h(x, y, z) = c.

Geometrically, this means:

• We are looking for the extreme values of f when (x, y, z) is restricted to lie on the curve of intersection C of the level surfaces g(x, y, z) = k and h(x, y, z) = c.

Suppose f has such an extreme value at a point $P(x_0, y_0, z_0)$.

We know from the beginning of this section that ∇f is orthogonal to C at P.

However, we also know that ∇g is orthogonal to g(x, y, z) = k and ∇h is orthogonal to h(x, y, z) = c.

So, ∇g and ∇h are both orthogonal to C.

This means that the gradient vector $\nabla f(x_0, y_0, z_0)$ is in the plane determined by $\nabla g(x_0, y_0, z_0)$ and $\nabla h(x_0, y_0, z_0)$

 We assume that these gradient vectors are not zero and not parallel. So, there are numbers λ and μ (called Lagrange multipliers) such that:

$$\nabla f(x_0, y_0, z_0)$$

$$= \lambda \nabla g(x_0, y_0, z_0) + \mu \nabla h(x_0, y_0, z_0)$$

In this case, Lagrange's method is to look for extreme values by solving five equations in the five unknowns

$$x, y, z, \lambda, \mu$$

These equations are obtained by writing Equation 16 in terms of its components and using the constraint equations:

$$f_x = \lambda g_x + \mu h_x$$
 $f_y = \lambda g_y + \mu h_y$ $f_z = \lambda g_z + \mu h_z$

$$g(x, y, z) = k \qquad h(x, y, z) = c$$

Find the maximum value of the function f(x, y, z) = x + 2y + 3z on the curve of intersection of the plane x - y + z = 1 and the cylinder $x^2 + y^2 = 1$

We maximize the given function subject to the constraints

$$g(x, y, z) = x - y + z = 1$$

$$h(x, y, z) = x^2 + y^2 = 1$$

The Lagrange condition is $\nabla f = \lambda \nabla g + \mu \nabla h$ So, we solve the equations

$$1 = \lambda + 2x\mu$$

$$2 = -\lambda + 2y\mu$$

$$3 = \lambda$$

$$x - y + z = 1$$

$$x^{2} + y^{2} = 1$$

Putting $\lambda = 3$ (from Equation 19) in Equation 17, we get $2x\mu = -2$.

Thus, $x = -1/\mu$.

• Similarly, Equation 18 gives $y = 5/(2\mu)$.

Substitution in Equation 21 then gives:

$$\frac{1}{\mu^2} + \frac{25}{4\mu^2} = 1$$

Thus,

$$\mu^2 = \frac{29}{4}, \mu = \pm \sqrt{29} / 2$$

Then,

$$x = 2 / \sqrt{29}$$

$$y = \pm 5/\sqrt{29}$$

 $y = \pm 5/\sqrt{29}$ and, from Equation 20,

$$z = 1 - x + y$$
$$= 1 \pm 7 / \sqrt{29}$$

The corresponding values of f are:

$$\frac{2}{\sqrt{29}} + 2\left(\pm\frac{5}{\sqrt{29}}\right) + 3\left(1\pm\frac{7}{\sqrt{29}}\right) = 3\pm\sqrt{29}$$

Hence, the maximum value of f on the given curve is:

$$3 + \sqrt{29}$$

The cylinder $x^2 + y^2 = 1$ intersects the plane x - y + z = 1 in an ellipse.

> Example 5 asks for the maximum value of f when (x, y, z) is restricted to lie on the ellipse.
